Ultrasound Guided Thoracic Paravertebral Block

In all ultrasound-guided paravertebral block techniques, an indication of correct needle tip placement is the anterior displacement of the parietal pleura when the solution of local
Ultrasound-Guided Paravertebral Block

Ultrasound guided thoracic paravertebral block is considered an INTERMEDIATE skill level block. Accurate needle tip visualization is ESSENTIAL at all times to avoid inadvertent pleural puncture or entry into the intervertebral foramen. In Plane Approach (Lateral to Medial)

USRA - Thoracic Paravertebral Block

Ultrasound-Guided Thoracic Paravertebral Block Experience in a Child. Paravertebral block is performed with the conventional loss of resistance technique. However, its use in children is limited compared to adults because it is difficult to predict the distance to the pleura and the loss of resistance in children,...

Ultrasound-guided thoracic paravertebral blocks
using a transversal transducer position, medial techniques. (A) Transversal cross-section at thoracic level T6 at the level of the inferior articulate process (IAP). The superior costotransverse ligament (SCTL, pink) is highlighted by a dotted outline.

Sonoanatomy relevant for thoracic paravertebral block. Transverse scan of the thoracic paravertebral region. For a transverse scan of the thoracic paravertebral region, the US transducer is positioned lateral to the spinous process with the orientation marker directed to the right side of the patient (Figure 3).

Editor—Ultrasound-guided thoracic paravertebral block (TPVB) is well described. The depth of the paravertebral space, the probe position, and the acute angle of needle trajectory renders the tip and
distal portion of the needle difficult to visualize while concurrently viewing the anatomical structures using conventional ultrasound techniques.

Ultrasound-Guided Thoracic Paravertebral Block. • In thin patients, the epidural space, the transverse process, the costotransverse ligament, and the pleura can be imaged in longitudinal view by placing the transducer lateral to the posterior spinous process and toggling from medial to lateral.

Thoracic paravertebral block (TPVB) is the technique of injecting local anesthetic alongside the thoracic vertebra close to where the spinal nerves emerge from the intervertebral foramen. This produces unilateral, segmental, somatic, and sympathetic nerve blockade, which is effective for anesthesia and in treating acute and chronic pain of...

Thoracic paravertebral block (PVB) is a well-established technique for perioperative analgesia in patients having thoracic, chest wall, or breast surgery or for pain management with rib fractures. Ultrasound guidance can be used to help identify the paravertebral space (PVS) and needle placement, and to monitor the spread of the local anesthetic.

Introduction. The block is of high quality and sufficient to provide analgesia for major surgery at various sites. A single site injection can provide blocks of 4-6 dermatomes. It can be performed at the Cervical, Thoracic or Lumbar level; however only the Thoracic Paravertebral block will be discussed here.

Thoracotomy needs adequate powerful postoperative analgesia. This study aims to compare the safety and efficacy of ultrasound (US)-guided serratus anterior plane block (SAPB) and thoracic paravertebral block (TPVB) for perioperative
